Abstract-Software component reuse has become of much interest in the software community due to its potential benefits, cost benefit, time saving, etc. which include increased product quality and decreased product development cost and estimated schedule. To select a component for reuse is very difficult because there are many components with approximate same name, same functionality etc. which make the reuse of component very time consuming. Hence there is required a technique which make the selection of component efficient and fast. For this purpose we proposed a scheme for the selection of software component which will be more efficient than existing scheme.

Keywords- Software Reuse, Systematic Software Reuse, Free Text Classification, Enumerated Classification, Faceted

1. INTRODUCTION

S oftware reuse is a process of creating software systems from the existing software rather than building them from low level design [1]. Software reuse is a fastest growing and very needy discipline today"s. Software reuse appears in various different forms from white-box reuse to black-box reuse, and from ad-hoc reuse to systematic reuse. In many different types software is reuse like SRS document, algorithm, design, source code, test case that are made during the software life cycle. Source code and tested modules are most commonly used. Many developer software reuses as the source code alone. Design reuse is popular in object oriented class libraries. The software community does not finalize what a software component exactly.

knowledge that improves in quality in every reuse, minimize the amount of development cost, development work needed for future projects and reduce in risk of future projects. A software component is an independent part of the software system having complete functionalities. Four levels of component reuse have been proposed:

- Design level products
- Analysis level products
- Code level components (modules, procedures, sub- routines, libraries, etc.)
 - Entire applications

2. TYPES OF REUSE

2.1 HORIZONTAL REUSE

Horizontal reuse refers to those software components that are used across a wide variety of applications in terms of code reuse of third-party applications or modules within a system, such as an e- mail, facebook access program. Various software libraries and repositories containing these code and documentation exist on the Internet today.

2.2 VERTICAL REUSE

The basic idea is the reuse of system functional areas, or domains that are potentially very useful, can be used by the systems with similar functionality [2].Domain engineering is "achieve iterative, comprehensive, life-cycle process that an organization can use to strategic business objectives. It increases the throughput of application engineering projects through the normalization of a product family and a related production process [3]. Domain engineering concentrations on the formation and preservation of reuse repositories of functional areas.

A software reuse process provides the facility the increase of quality, productivity and reliability, and the decrease in Implementation, time and development cost also. There is only investment in to start a software reuse process, but after that investment recovers in only few reuses. In short, the reuse process's development and reuse repository produces a

2.3 SYSTEMATIC SOFTWARE REUSE

Systematic software reuse and the reuse of components impact almost the whole software development process [2]. Software process models were established to provide guidance in the creation of high-quality product at predictable costs. Software process models are adapted based on experience, changes and improvements were suggested by classic waterfall model. New models are also based on efficient reuse of useful components that have been developed in other projects [2].

3. SOFTWARE COMPONENT

Component is fundamental unit of a software construction. Every component has its own interface and an Implementation. The followings are the exclusive aspects of a Software Component that must not only be described, but also searchable:

- Version data
- OS/Platform compatibility
- Development
- Scalability
- Testing specification, and performance data
- Known deficiencies
- Functional specification
- Interface specifications
- Use cases, use scenarios
- Supportability data
- Evaluations

3.1 REUSABLE SOFTWARE COMPONENT

A component is an autonomous part of software that interacts with other components in a definite manner to accomplish a specific task. Components can be used to build both shrinkwrap software and enterprise critical software [5]. Reusable software points to that software components can be combined with a variety of programs without modification. Reusable software components are designed to take benefit of reusability in software construction. Software reuse is the use of knowledge or artifacts from existing software components to build a new software system. There are numerous work products that can be reused, for example designs, specifications, architectures, source code and documentation [4]and[6].

4. EXISTING METHODS OF COMPONENTS CLASSIFICATIONS

What is Component classification: reusable software item is generally known as a component. Components may consist of, ideas, designs, source code, linkable libraries and testing strategies but they are not necessary. In classification, the developers have to specify what components or what type of components they want. These components then should be retrieved from a library, evaluated as to their suitability, and improved if required. When the developer is satisfied that they have retrieved a appropriate component, then it can be added to the current system under development. The aim of a component retrieval system [5] is to make able to located either the exact component necessary, or the closest match, in the minimum amount of time, by using a suitable query. The retrieved component(s) should available for possible selection.

Classification is the process of selecting of interest. The classification of components for reuse is more difficult than classifying books in a library. A library system always uses structured data for its classification system (e.g., the Dewey Decimal number). Current classification process to classify software components divided into the following categories: Free text, enumerated, attribute-value, and faceted. The selection of each of the methods is evaluated as to how well they perform against the described criteria for a good retrieval system.

4.1 FREE TEXT CLASSIFICATION

Free text retrieval is based upon a keyword search. In this type classification technique, a user inputs keywords to search. The retrieval system does searches using the text contained within documents [7]. indexes are searched to try to find an suitable entry for the required keyword and as a result a ranked list of documents is returned. The ambiguous nature of the keywords is major drawback of this method. Another disadvantage is that a search returns many irrelevant components as a result. An example of free text retrieval is the "grep" command of UNIX operating system. This type of classification makes large expenses in the time taken to index the components, and the time taken to make a query. All the relevant text in each of the documents related to the components are index, which must be searched from starting to end when a query is fire. Relevant keywords are derived by their statistical and positional properties, thus resulting is called automatic indexing. Two processes indexing and searching are involved in keyword search. Keyword search provides a freedom to users to freely submit their query to search engines.

4.2 ENUMERATED CLASSIFICATION

Enumerated classification is a single dimensional classification that uses a set of mutually exclusive classes [9].

An example of this is the Dewey Decimal system that is used in a library to classify books [8].Each subject area, e.g. Mathematics, physics, computer related etc, has its own classifying code. Sub code further represents a specialist subject area within the main subject. These codes can further sub coded by author or publisher. This classification method has their own advantages and disadvantages pivoted around the concepts of a unique classification for each item. The classification scheme allow a user to find more than one item that is classified within the same division/ subdivision

assuming that if more than one exists. For example, there may be more than one book of a subject, each published by different publishers. Major problem in this type of classification schemes as is one dimensional do not allow flexible classification of components into more than one place for reusable software components. However it provides significant support for best effort retrieval of components.

4.3 ATTRIBUTE VALUE

The attribute value classification scheme uses set of attributes to classify a component [10]. For an example, a book has many attributes such as the publisher, the author name, a unique ISBN number and classification code in the Dewey Decimal system. These are the only example of the possible attributes. Based on the search query of reader a book can be combed in no. of ways e.g. number of pages, the size of the paper used, the type of print face, the publishing date, etc. clearly, the attributes relating to a book can be:

• Bulky-All possible combinations of attributes could run into many tens, which may not be known at the time of classification.

• Multidimensional-The book can be classified by different attributes in different places.

4.4 FACETED

Faceted classification was proposed by Prieto-Diaz and Freeman in 1987[11] also known as faceted navigation or faceted browsing that relies on facets which are mined by experts to describe the features about components ex:-Features, such as the component's functionality, how to run the component, and implementation details. Like attribute classification method, various facets are used to classify components however there are usually a lot fewer facets than there are potential attributes. Sometimes users are given choice to select features for search. This helps the users to achieve his search goals rapidly and efficiently. Faceted classification and retrieval has verified to be very effective in retrieving reuse component from repositories. Ruben Prieto-Diaz has proposed a faceted scheme that uses six facets.

• The functional facets are: Function, Objects and Medium.

• The environmental facets are: System type, Functional area, setting [1].

Each facet has to have values assigned at the time the component is classified.

Faceted classification scheme is very attracting the most attention within the software reuse community. Like the attribute classification method, facets classify components however there are generally a lot fewer facets than there are potential attributes.

Each of the facets has values assigned at the time the component is classified.

The individual components can then be distinctively identified by a tuple, for example < add, arrays, buffer, database manager, billing, book store >

Frakes and Pole conducted an investigation on the above classification methods [9]. The investigation found no any major differences between the four different classification schemes, however, the following about each classification method was noted:

Free text classification

-Ambiguous, indexing costs

• Enumerated classification

-Fastest method, difficult to expand

• Attribute value classification

-Slowest method, no ordering,

Faceted classification

-Easily expandable, most flexible

5. PROPOSED SYSTEM

Various kinds of classification schemes are available to classify a component. But one problem is how to implement this, many systems follow the principle: Once a new component has been identified, a administrator is responsible for the classification should be proficient. The system is employed for two reasons. First, the administrator must know how to classify the components according to the scheme. Second, a lexicographical consistency is necessary across the whole of the system. The classification system is always separate to the retrieval system, which is for the users. Well-known systems works with one classification and retrieval scheme, such as enumerated or faceted. Others work with a different classification system.

In this research, we propose a new classification scheme that integrates the features of existing classification schemes. Proposed algorithm includes:

Step1: Take the query from the user.

Step2: Apply the enumerated classification scheme on the reuse repository.

Step3: Store their result in temporary buffer.

Step4: Apply the attributed value classification on the buffer.

Step5: Return the result on the query interface.

In this system (Figure 1) the administrator sets up the proposed scheme. The developers develop and put their components into library. The developer can also retrieve components from the library. Query tracking system should be maintained to improve the proposed scheme. The proposed system will provide the following functionality to the users.

- Storing components
- Searching components
- Browsing components

Each of the four main classification schemes has both advantages and disadvantages. The free text classification method does not offer the flexibility and has many problems with synonyms and search spaces. The faceted classification method offers the most flexible method of classifying components and has problems when trying to classify similar components for use. The enumerated classification scheme provides a fast way to drill down into a library, but does not offer the flexibility to classify components for use in more than one way. The attribute value classification scheme permits multidimensional classification of the same component, but does not offer any ordering of the different attributes.

Our solution to these problems would be to use an enumerated classification scheme combined with attribute value classification scheme to classify the components details. The enumerated scheme is initially used to reduce the search domains. Among the available components in the repository only components selecting by enumerated scheme are considered for attribute value scheme by reducing the size of the search domain attribute value have to search in limited domain so it gives the more accurate results and efficiently.

Figure 1 shows the architecture of proposed system. The repository is library of components and their information. Users are provided interface through which they can interact with components. To upload a component User will provide the details. To retrieve a component the user will give his query or he will give details so that the system will provide the matching components.

6. Conclusion

In this paper four classifications (free text, attribute value, enumerated and faceted classification) are examined and opened their advantages and disadvantages. The proposed system takes advantage of each classification scheme. An efficient software tool with user friendly interface is purposed with integrated classification scheme which restricts search space and reduces search time increasing the efficiency of classification of software component.
