Abstract - In this era of internet, the Online Social Networks (OSNs) are the platform to build social relations among people who share interests, activities, backgrounds or real life connections. OSNs have gained a ubiquitous status and this has led to security issues of posting unwanted messages on user wall. Therefore, in order to make the OSN user wall a secured wall, we are introducing a flexible - rule based system which provides users to control the messages that are posted on their walls and allows user to customise the filtering criteria to be applied on their walls. This system exploits machine learning based soft classifier for automatically labelling messages in support of content based filtering.

Keywords- Online Social Networks, Flexible-rule based system, filtering criteria, Machine – learning based soft classifier, content based filtering.

I. INTRODUCTION

The Online Social networks have become a necessity in our daily life. The OSNs are a popular medium of interaction where large amounts of human information are disseminated. Several contents such as audio, video, texts, images etc are shared on a daily basis. The statistics of facebook says, an average user creates 90 pieces of contents each month, whereas more than 30 billion pieces of content are shared each month. This has led to the breach of privacy on OSN user wall and as a consequence the user might face the issue of unwanted messages on their walls.

Therefore in order to prevent the unwanted messages to be posted on OSN user wall information filtering is used. Thus, the proposed system uses a flexible rule based filtering that allows user to customise the filtering criteria that is to be applied to their walls.

This service is not only a matter of using web content mining techniques for different application, rather it requires to design additional classification strategies and also wall post comprises of short text and traditional methods have limitations. Here the short texts are separated and categorised based on its content using machine learning text categorization that automatically assigns short texts to a set of categories.

The motive of this work is to propose an automated system called Filtered Wall (FW). This system provides the user the privilege to control the messages that are posted on their walls.

We make use of neural learning as far as learning model is concerned. This is one of the best solutions in text classification. We base the overall short text classification strategy on RBFN for their proven capabilities in acting as soft classifier.

Our model implements a hierarchical two level classification strategy. In the first level the RBFN classifies the messages into neutral and non-neutral. In the second level, the non-neutral messages are classified producing gradual estimates of appropriateness to each category. After the classification is done, the filtering rules are applied.

Filtering rules give the result of ML categorisation process, which filter the user wall and relationship of user. In addition, the system provides the support for user defined black lists (BLs) that is lists of users that are temporarily prevented to post any kind of messages on OSN user wall.

The two fundamental concepts are Content Based Filtering and Short Text Classifier as explained below:

A. Content Based Filtering

An Information Filtering system is a system that eliminates the redundant or unwanted information from a stream of dynamically generated dispatched asynchronously by an information producer and present to the user those information that are likely to satisfy his/her requirements. It derives the information from the correlation between the information contents and the user preferences. The documents processed in content based filtering are somewhat similar to text classification. It exploits Machine Learning paradigm according to which a classifier is automatically induced by learning from a set of pre-classified examples.

B. Short Text Classifier

The short Text Classifier is a technique used for classifying short texts. It is based on neutral learning strategy to semantically categorise short texts. From ML point of view, this task requires a hierarchical two-level strategy. In the first level it classifies the sentences as...
neutral and non-neutral. Then it classifies and eliminates the neutral sentences. In the second level classifier acts on non-neutral short texts and for each of them it simply produces estimated appropriateness or gradual membership for each of the conceived classes, without taking any hard decision on any of them. Such a list of grades is then used by the subsequent phases of the filtering process.

Let us take a look at the example as follows:

### II. SYSTEM ARCHITECTURE

The OSN architecture is three-tier architecture. The first layer of the architecture is Social Network Manager (SNM). The aim of SNM is to provide basic OSN functionalities (i.e. profile and relationship management). The second layer provides the support for external Social Network Applications (SNAs). SNAs may in turn require an additional layer for graphical user interface (GUIs). According to the architecture the proposed system is placed in the second and third layers. The users interact through GUIs, which provides users with FW, a wall where messages authorised by FRs/BLs are published. The fundamental components of the proposed system are Content-Based Message Filtering and Short Text Classifier (STC) modules. Then the latter classifies the messages into different categories. CBMF exploits the messages classified by STC in order to enforce FRs specified by the user. BLs can also be added to improve the filtering process. Given below is the summarised working of the given architecture:

1) After entering the private wall of one of his/her contacts, the user tries to post a message, which is intercepted by FW.
2) A ML-based text classifier extracts metadata from the content of the message.
3) FW uses metadata provided by the classifier, together with data extracted from the social graph and users’ profiles, to enforce the filtering and BL rules.
4) Depending on the result of the previous step, the message will be published or filtered by FW.

### III. FILTERING RULES AND BLACKLISTS

Here we are going to describe and elaborate the filtering rules and then we illustrate the blacklists. We are going to map the social network to the directed graph in which each node corresponds to the user whereas the edges denote the relationship between the nodes. The edges represent the trust level between two users, that is, how much a given user considers the trustworthy with respect to that specific kind of relationship the user with whom he/she is establishing the relationship.

We assume that the trust levels are the rational numbers in the range [0, 1]. Let us say, there exists a direct relationship of the given type RT and trust value X between two users, if there is an edge connecting them having the labels RT and X. moreover, two users are in an
indirect relationship of a given type RT if there is a path of more than one edge connecting them, such that all the edges in the path have label RT. There are many algorithms to compute trust values. Such algorithms mainly differ on the criteria to select the paths on which trust computation should be based, when many paths of the same type exist between two users.

A. Filtering Rules

We consider three main different issues in defining the language for FRs specification that should affect the message filtering decision. When we talk about OSNs then it may happen that the same message may have different meaning and relevance based on who writes it. Therefore FRs must give the users the privilege to put constraints on message creators.

There are various criteria through which message creators can be identified. There are the options formalised to specify the creators, defined as follows:

Definition 1. (Creator specification). A creator specification creator Spec implicitly denotes a set of OSN users. It can have one of the following forms, possibly combined:

1) a set of attribute constraints of the form an OP av, where an is a user profile attribute name, av and OP are, respectively, a profile attribute value and a comparison operator, compatible with an’s domain.

2) a set of relationship constraints of the form (m; rt; minDepth; maxTrust), denoting all the OSN users participating with user m in a relationship of type rt, having a depth greater than or equal to minDepth, and a trust value less than or equal to maxTrust.

Definition 2. (Filtering rule). A filtering rule FR is a tuple (Author, creatorSpec, contentSpec, action), where:

- author is the user who specifies the rule;

- creatorSpec is a creator specification, specified according to Definition 1;

- contentSpec is a Boolean expression defined on content constraints of the form (C, ml), where C is a class of the first or second level and ml is the minimum membership level threshold required for class C to make the constraint satisfied;

- Action ∈ {block; notify} denotes the action to be performed by the system on the messages matching contentSpec and created by users identified by creatorSpec.

B. Blacklists

BLs is a mechanism to prevent messages from unwanted users. They are directly managed by the system through a set of rules called BL rules. BL rules allow the users to identify and block the unwanted users according to their profile as well as their relationships in the OSN. The BL rules give the user the privilege to proscribe the user from their wall, they do not know directly or any user they know and have a bad opinion about them. The users are proscribed for a limited time span. The BL rules are formally defined as follows:

Definition 3. (BL rule). A BL rule is a tuple (Author, creatorSpec, creatorBehavior, T), where:

- Author is the OSN user who specifies the rule, i.e., the wall owner;

- creatorSpec is a creator specification, specified according to Definition 1;

- creatorBehavior consists of two components RFBlocked and minBanned. RFBlocked = (#bMessages, mode, window) is defined such that:

- RF = #bMessages

  #bMessages, where #tMessages is the total number of messages that each OSN user identified by creatorSpec has tried to publish in the author wall (mode = myWall) or in all the OSN walls (mode = SN); whereas #bMessages is the number of messages among those in #tMessages that have been blocked;

- window is the time interval of creation of those messages that have to be considered for RF computation;

- minBanned = (min, mode, window), where min is the minimum number of times in the time interval specified in window that OSN users identified by creatorSpec have to be inserted into the BL due to BL rules specified by author wall (mode = myWall) or all OSN users (mode = SN) in order to satisfy the constraint.

- T denotes the time period the users identified by creatorSpec and creatorBehavior have to be banned from author wall.

Example 3. The BL rule:

(Alice; (Age < 16); (0.5; myWall; 1 week); 3 days) inserts into the BL associated with Alice’s wall those young users (i.e., with age less than 16) that in the last week have a relative frequency of blocked messages on Alice’s wall greater than or equal to 0.5. Moreover, the rule specifies that these banned users have to stay in the BL for three days. If Alice adds the following component
(3, SN, 1 week) to the BL rule, she enlarges the set of banned users by inserting also the users that in the last week have been inserted at least three times into any OSN BL.

IV. EVALUATION

A system will automatically filter unwanted messages from OSN user walls on the basis of both message content and the message creator relationships and characteristics. The paper substantially extends for what concerns both the rule layer and the classification module. Major differences include, a different semantics for filtering rules to better fit the considered domain, an online setup assistant (OSA) to help users in FR specification, the extension of the set of features considered in the classification process, a more deep performance evaluation study and an update of the prototype implementation to reflect the changes made to the classification techniques. In web mining the most general sense it can contribute to the increase of profits, be it by actually selling more products or services, or by minimizing the costs. In order to do this, marketing intelligence is required. This intelligence can focus on marketing strategies and competitive analyses or on the relationship with the customers. The different kinds of web data that are somehow related to customers will then be categorized and clustered to build detailed customer profiles. This not only helps companies to retain current customers by being able to provide more personalized services, but it also contributes in the search for potential customers.

V. CONCLUSION

In this paper, we propose a system to filter unwanted messages from OSN walls. On-line Social Networks (OSNs) is to give users the ability to control the messages posted on their own private space to avoid any unwanted content to be displayed on the user wall. Up to now OSNs provide little support to this requirement. To fill the gap, we enhance the system by creating an instance randomly notifying a message system that should instead be blocked, or detecting modifications to profile attributes that have been made for the only purpose of defeating the filtering system. Additionally, we plan to investigate the use of online learning paradigms able to include label feedbacks from users. Additionally, we plan to enhance our system with a more sophisticated approach to decide when a user should be inserted into a BL. The development of a GUI and a set of related tools to make easier BL and FR specification is also a direction we plan to investigate, since usability is a key requirement for such kind of applications. We would like to remark that the system proposed in this paper represents just the core set of functionalities needed to provide a sophisticated tool for OSN message filtering. Moreover, we are aware that a usable GUI could not be enough, representing only the first step. Indeed, the proposed system may suffer of problems similar to those encountered in the specification of OSN privacy settings. As future work, we intend to exploit similar techniques to infer BL rules and FRs. Additionally, we plan to study strategies and techniques limiting the inferences that a user can do on the enforced filtering rules with the aim of bypassing the filtering system, such as for instance randomly notifying a message that should instead be blocked, or detecting modifications to profile attributes that have been made for the only purpose of defeating the filtering system.
